

# Generator wind power loss

## Overview

---

Turbine-wake and farm-atmosphere interactions can reduce wind farm power production. To model farm performance, it is important to understand the impact of different flow effects on the farm efficiency (i. Global wind capacity is expected to reach 1,800 GW by 2030 [2]. The generator system in wind turbines performs the critical function of converting mechanical power (torque  $\times$  speed) to electrical power (electrical current  $\times$  voltage). A typical drivetrain configuration within a turbine nacelle is. The gross energy production is the energy production of the wind farm obtained by calculating the predicted free stream hub height wind speed distribution at each turbine location and the manufacturer's supplied turbine power curve. These losses occur due to various factors, including resistance in transmission lines and cables, inefficiencies in transformers and.
